Data Analysis Job Market Report

Omolayo Arogundade Feb. 5, 2026

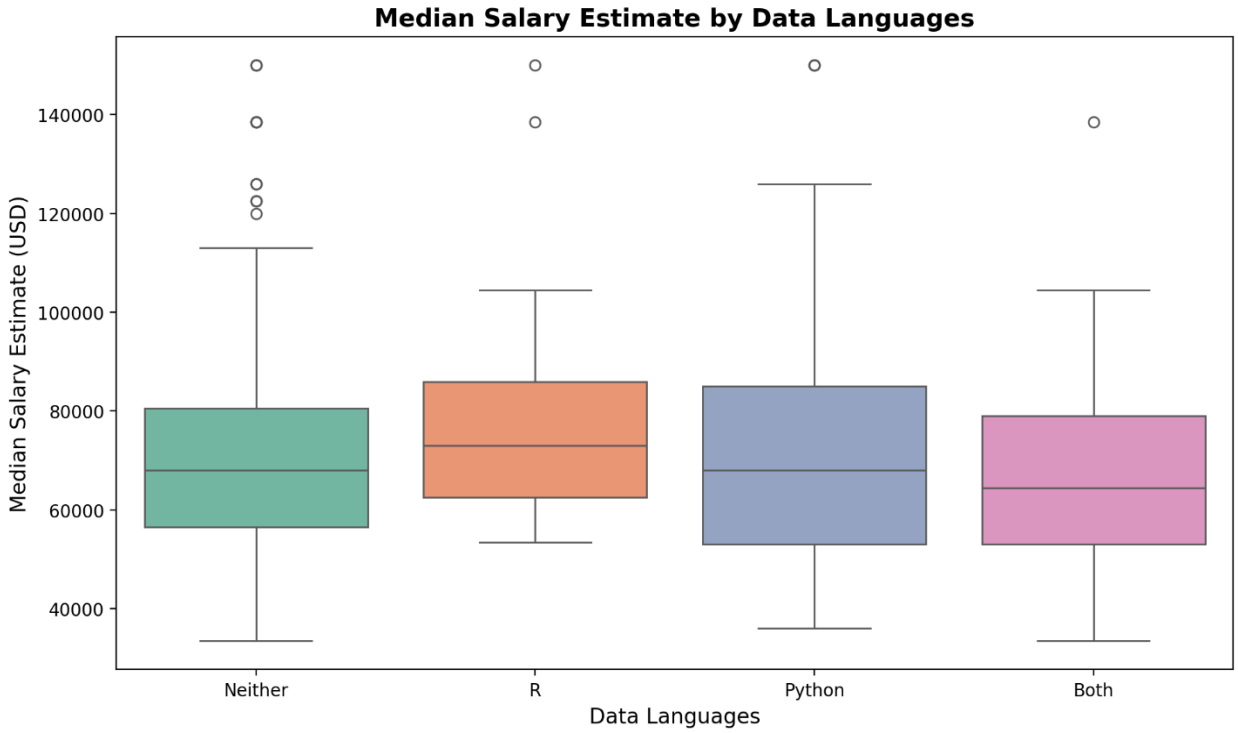
Introduction: This report analyzes job-posting data to examine how required experience levels and programming-language proficiencies affect salary, offering actionable insights for job seekers, employers, and educators on current compensation trends.

Analysis

- Scatter Plot: Minimum Years of Experience vs. Median Salary Estimate
- Box Plot: Median Salary Estimate by Data Languages

This scatter plot shows the relationship between minimum years of experience required and median salary estimates. The plot includes 185 data points (after removing entries with missing experience data).

The plot presents no significant influence of the years of experience on the salary in the data analyst roles. This suggests the presence of other underlying factors and skills beyond the scope of this analysis.



The box below analyzes how different language combinations of **R only, Python only, both, or neither** relate to compensation and experience levels. This analysis equips job seekers with clarity on which technical skills command higher pay and helps employers benchmark competitive compensation.

The box plot indicates only a modest association between programming-language knowledge and salary. Jobs requiring R show a modest salary premium, while listings that specify both R and Python unexpectedly correspond to lower median pay.

Reflection: Experience remains a key factor in shaping salary outcomes. While it is important to note that the sample size may not be representative enough to draw a holistic conclusion, job seekers should prioritize matching each application to match the specific skills and experience requirements of the role.
